

INSTALLATION • OPERATION • MAINTENANCE

INSTRUCTIONS

TYPE ALS AND DLS POWER SUPPLIES

CAUTION

Before putting carrier equipment into service, it is recommended that the user of this equipment become acquainted with the information in these instructions. This supply module should not be removed or inserted while the cabinet is energized with dc quantities. Failure to observe this precaution can result in undesired operation or component damage.

Some components used on this module are sensitive to and can be damaged by the discharge of static electricity. Electro-static discharge precautions should be observed when handling modules or individual components.

APPLICATION

The ALS and DLS power supply modules isolate the relay system logic and sensing circuits from the station battery. The ALS module provides a source of plus and minus 15 Vdc needed by the operational amplifier and digital logic circuits, while the DLS module provides the additional +15 Vdc capacity for driving large amounts of digital logic circuits and for extra trip outputs.

CONSTRUCTION

The ALS and DLS modules are self-contained power supplies with isolated outputs. The supplies consists of an inverter, rectifier assembly or assemblies, and feed-back regulator that is sam-

pled on the main +15V supply for both the ALS and DLS modules. The -15V supply on the ALS is a shunt regulated supply.

All the circuitry for both supplies are housed in modules approximately 4.875" x 10" x 2" and have 2" panels on which are mounted power ON-OFF switches, fuses, LED indicators, test jacks, and output adjusters. Except for the connectors, the modules are completely enclosed in aluminum cases which serve both as heat sinks and RFI noise shields. Each supply requires 2 module spaces in the standard 3 rack unit chassis and is designed to fit in any position in the chassis.

RATINGS

DC Input

Nominal

48V.....	38 to 66 volts d.c. @ 2.6 Amps
125V.....	80 to 145 volts d.c. @ 1.4 Amps
250V.....	170 to 290 volts d.c. @ 0.6 Amps

DC Output

ALS Supply.....	+15 volts @ 3 Amps Max. -15 volts @ 1 Amp Max.
DLS Supply.....	+15 volts @ 4 Amps Max.

Regulation on the +15 volt supplies is \pm 150 mV. Regulation on the -15 volt supplies is \pm 450 mV.

NOTE: All ratings are at rated loads.

All possible contingencies which may arise during installation, operation, or maintenance, and all details and variations of this equipment do not purport to be covered by these instructions. If further information is desired by purchaser regarding his particular installation, operation or maintenance of his equipment, the local Westinghouse Electric Corporation representative should be contacted.

OPERATION

Referring to the Block Diagram Figure 1, the secondary side is to the right while the primary side is to the left. Rated DC input voltages are applied to terminals 33 for battery positive and 35 for battery negative which goes through the switch and fuses. During operation, any noise generated by the power supply or noise on the battery supply lines is attenuated by the common and differential mode noise rejection circuits. An energy storage capacitor is used to limit the effect of transitory input voltage fluctuations. The input voltage is also sensed for protection against overvoltage. The DC input light emitting diode is illuminated to indicate presence of the input voltage.

The switching signal from the control logic is applied to the pulse width modulator driver which in turn switches the primary of the transformer. The resulting secondary waveform is rectified and filtered at a sufficient voltage level that will sustain secondary circuit operation. The voltage level detection circuit disables the start up oscillator through an optical isolator and also enables the pulse width modulator circuit to produce a 27.5 kilohertz switching signal. This signal from the pulse width modulator is coupled by a second optical isolator to the primary control logic which is then applied to the pulse width modulator driver and the transformer primary is switched.

The switching frequency is always 27.5 kilohertz. However the "ON" time of the primary, which is the width of the pulse, is a function of the output voltage under load conditions. Power fold back protection operates whenever the output load demand is greater than the power supply rating. The overload condition is constantly sensed by the power fold back memory and allows normal operation once the overload condition is removed. The pulse width applied to the driver through the control logic during overload conditions is less than the pulse width under normal loads, which insures the safe operation of switching components.

DESCRIPTION

Referring to schematic drawing Figure 2A (ALS supply), the balun transformer T1 acts to

suppress any noise that is of the same phase on both leads from the battery, or from the switching supply back through the leads. D1 protects against accidental battery polarity reversal or transient battery reversal while C7, L1, and C2 suppress differential mode noise. Resistor R1 limits the inrush current to the supply and C1 stores energy to allow uninterrupted operation even when the dc input voltage experiences transients.

Z1, R9, R10, C9 and Q5 form an overvoltage shutdown circuit to limit the stress on components when subjected to prolonged overvoltage. Whenever the input voltage is too great, Z1 conducts turning on Q5, which blocks the signal at the gate of Q4 (the main switching device) through IC1, Q2, and Q3.

When the input DC voltage is applied, light emitting diode D2 is turned on. Z1, Q1, and associated circuitry will keep the startup oscillator disabled until a positive 15 volts is obtained at test point one. Once the 15 volts is there, the startup oscillator is enabled and a 25 kilohertz switching signal is applied to the control circuit IC1 pin 2. This signal is applied by IC1 to transistors Q2 and Q3, providing a low impedance source and sink to drive the gate of the mosfet Q4. Components C6, R6, and D3 form a circuit to allow core recovery of the T2 transformer. Zener diodes Z3 and Z7 prevent excessive voltage from appearing at the drain of the mosfet Q4 while R8 and C8 suppress transient ringing. Resistor R7 functions as a current sensor. When an overcurrent condition occurs at a level which is determined by the adjustment of P1, Q6 is biased on, SETTING flip flop IC2. This causes the mosfet to turn off immediately. The flip flop will remain in this state until the arrival of the next switching pulse from the pulse width modulator IC5. The arrival of this switching pulse will reset the flip flop and allowing the mosfet to conduct. If the overcurrent condition still exists the flip flop will be set again. As a result the mosfet will be switched on and off until the overcurrent condition is removed.

The conduction time of the mosfet is inversely proportional to the overcurrent magnitude. That is, the more severe the overcurrent the shorter the mosfet conduction time. This characterizes a unique feature known as power fold back in the power supply design.

Components D6, R22, C13, R23 and D7 along with a transformer winding form a circuit which provides auxiliary power to the primary side circuitry after startup. The secondary voltage is rectified by the fast recovery diodes - D9 and D10 for the negative supply and D11 and D12 for the positive supply. Filter circuits L2, C16, and L3, C19 produce the final supply voltages. During initial power up, the voltage rises on the secondary and charges capacitors C21 and C22 through D13. When this voltage rises above 10 volts, zener diode Z8 conducts turning on transistors Q7 and Q8. Q7 turns on optical isolator IC4, which disables the startup oscillator and at the same time enables the pulse width modulator IC5 to produce a switching signal at test point 9. This signal is adjusted to 27.5 kilohertz by potentiometer P2.

The positive output voltage level, which is also controlled by IC5, is adjusted to 15 volts by potentiometer P3, referred to as "OUTPUT ADJUST" on the front panel of the module. The negative 15 volts tracks the positive voltage by comparing both voltage levels in one section of operational amplifier IC6, which biases shunt regulator Q11 in order to regulate the negative 15 volt output.

The switching signal at TP9, is coupled to the primary through optical isolator IC3. The output of the optical isolator is applied to the control circuit and then to the gate drive of the mosfet.

The output voltage of the power supply is monitored for over and undervoltage. The under and overvoltage is sensed by two sections of integrated OP-AMP circuit IC6. When an unfavorable voltage level exists, pins 1 or 7 of IC6 will go low removing the base drive from Q10 thereby causing output LED D21 to turn off and alarm relay RR1 to drop out. In addition, bias is applied to transistor Q9 to drop the normal 10 volt PSME signal to a low of less than 4 volts. The PSME signal is used to control logic circuits elsewhere in the relay system.

The DLS power supply provides additional isolated +15 volt capacity for powering large numbers of digital logic circuits and for extra trip outputs. The internal schematic for the DLS is shown in Figure 2B. It does not include circuits

for the generation of -15 volts. Otherwise, the construction and circuitry is identical to that for the ALS power supply. Deleted are the shunt regulator Q11 and the tracking voltage comparator IC6. In addition, the two secondary windings of T2 are paralleled to achieve the 60 watt power capability for the +15 volt output.

ACCEPTANCE CHECK

Equipment Required:

- (a) Digital Voltmeter (DVM)
- (b) 5 ohm and 15 ohm loads for ALS supply and 3.75 ohm load for DLS supply. All loads should be rated 100 watts.

1. Input Voltage Range Check

- A. Apply rated voltage to terminals of supply.
- B. Turn on the power supply switch.
- C. The DC INPUT light should come on.
- D. Raise the input voltage to the voltage value from the table below and the DC OUTPUT light should go out:

(Caution should be observed to apply the excess voltage for less than 1 second to prevent undue stress on components.)

1349D85A01, A04, A07	85V
1349D85A02, A05, A08	200V
1349D85A03, A06, A09	350V

- E. Lower the input voltage to the value from the table below and the DC OUTPUT light should remain on.

1349D85A01, A04, A07	38V
1349D85A02, A05, A08	80V
1349D85A03, A06, A09	170V

2. Output Voltage Checks

- A. Apply rated nominal voltage to the input terminals of the supply.
- B. Turn on the power supply switch.

- C. Measure the open circuit voltage at terminals 21 (+) and 31 (com) with a digital voltmeter. The voltage should be +15 VDC. "OUTPUT ADJUST" potentiometer (P3) can be used to adjust the output to +15 VDC. The -15 VDC output on the ALS supply should track the +15 volt output within $\pm .10$ volts.
- D. Next load the outputs of the supplies per the following table.

ALS Supplies

+15 volt output – 5 ohms, 100 watts –
3 Amps
-15 volt output – 15 ohms, 100 watts –
1 Amp

DLS Supplies

+15 volt output – 3.75 ohms, 100 watts –
4 Amps

The output voltages should not change from their adjusted open circuit values by more than 0.150 volts. No alarms should occur and the DC output LED should remain lit as the load is changed from full to no load.

REPAIR CALIBRATION

NOTE: If the power supply is determined to be misoperating, it is recommended that the supply be sent back to the factory for repair. However, if repairs must be made in the field, the following test and calibration procedure should be used.

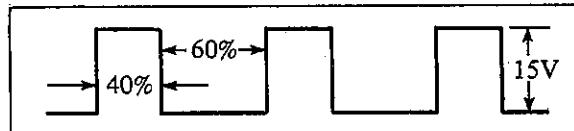

Equipment Required:

- (a) Oscillator (Dual trace).
- (b) Frequency Counter.
- (c) Digital voltmeter.
- (d) Separately adjustable +15 VDC and -15 VDC power supplies.
- (e) 0-350 VDC power supply.
- (f) Loads specified for the Acceptance Check.

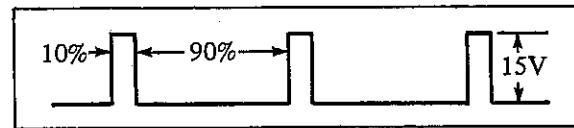

1. This portion should be done on a test bench and should be done only if it is suspected that the supply is misoperating.

Remove the cover and open at least two leads to the MOSFET Q4 (the left hand transistor when the case is open and the connector is to the right). Refer to internal schematics Figs. 2A and 2B.

2. Connect the DVM between TP1 and common. Apply rated nominal input voltage to terms 33 and 35. The DVM should measure +15 volts at TP1.
3. The waveform at TP3, monitored on an oscilloscope, should be a square wave pulse train with an approximately 40% duty cycle on the positive portion at a frequency of 25000 to 26000 Hz (Fig. A). The waveform at TP2 is the inverse of that at TP3.

*Fig. A*

4. Next, monitor TP3 with an oscilloscope. Jumper TP4 to TP3 and the waveform at TP3 will change to a positive duty cycle of less than 10% (Fig. B). Remove jumper and the waveform will return to the normal 40% duty cycle.

*Fig. B*

5. Raise the input voltage to the value from the table below and the waveforms at TP2 and TP3 should disappear.

1584C88A01, A04, A07 – 85V
1584C88A02, A05, A08 – 200V
1584C88A03, A06, A09 – 350V

6. Next, lower the input DC voltage till 9 VDC is measured at TP1 with a digital voltmeter. The startup oscillator is disabled and the waveform at TP2 will disappear.
7. Turn off the input power supply.

8. For ALS (± 15 VDC) Power Supplies

- (a) With external adjustable +15 VDC and -15 VDC power supplies, apply + and - 14.5 VDC to the output terminals of the ALS supply. Use a DVM for measurement. The LED (D21) will be turned on.
- (b) Monitor TP9 with a frequency counter and adjust the frequency with potentiometer (P2) to 27.5 KHz $\pm .01$ KHz. Lower the positive voltage from +14.5 VDC to +7 VDC and the waveform at TP9 will be disabled. Bring the voltage back to +14.5 VDC.
- (c) Monitor output terminal 11 to common with a DVM. The voltage should be 13.8 VDC (± 1 VDC).
- (d) Monitor output terminal 13 to common. The voltage should be 9 VDC or greater. Increase the +14.5 VDC to +16.4 VDC. The voltage at terminal 13 will drop to 1 VDC or less and LED (D21) will turn off. Lower the +14.5 VDC to 13.4 VDC and terminal 13 will drop to 1 VDC or less and LED (D21) will turn off. Return the positive voltage to +14.5 VDC and follow the same procedure for the -14.5 VDC.

9. For DLS (+15 VDC) Power Supplies

Follow the same procedure as that in 8 (a), (b), (c), and (d) except references to -15 VDC do not apply.

- 10. Apply rated voltage to the input terminals while maintaining the ± 14.5 VDC for ALS

supplies and +14.5 VDC for DLS supplies at the output terminals. With an oscilloscope monitor TP11. The signal at TP11 (Fig. C) will be 27.5 KHz waveform generated by IC5 and isolated from the secondary by IC3. IC4 will shut down the startup oscillator creating a +15 VDC level at TP2.

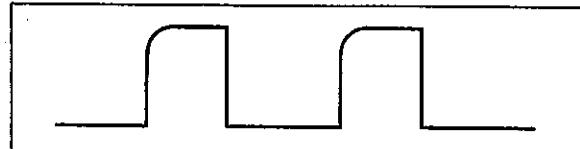

Fig. C

- 11. Monitor TP3 for the 27.5 KHz waveform (Fig. D).

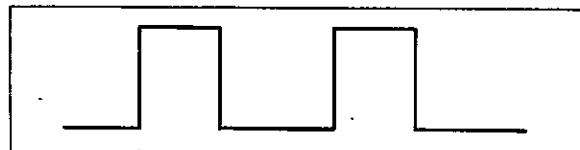

Fig. D

- 12. Remove all external voltage supplies and re-connect the proper leads to Q4.
- 13. Replace cover and then perform the Acceptance Check.

RENEWAL PARTS

Repair work can be done most satisfactorily at the factory. However, interchangeable parts can be furnished to the customers who are equipped for doing repair work. When ordering parts, always give the complete nameplate data and appropriate Westinghouse Style Number.

INSTALLATION • OPERATION • MAINTENANCE
INSTRUCTIONS

TYPE ALS AND DLS POWER SUPPLIES

This addendum reflects changes to the electrical parts lists on pages 9 and 10 for ALS and pages 13 and 14 for DLS Power Supply. Changes are identified by (*).

ADDENDUM TO IL 41-830.11

EFFECTIVE OCTOBER 1986

All possible contingencies which may arise during installation, operation, or maintenance, and all details and variations of this equipment do not purport to be covered by these instructions. If further information is desired by purchaser regarding his particular installation, operation or maintenance of his equipment, the local Westinghouse Electric Corporation representative should be contacted.
